*k*-out-of-*n* systems

# k-out-of-n systems

A k-out-of-n system is a binary monotone system  $(C, \phi)$  where  $C = \{1, \ldots, n\}$  which functions if and only if at least k out of the n components are functioning.

Let the component state variable of component i be  $X_i$ ,  $i \in C$ , and let the vector of component state variables be  $\mathbf{X} = (X_1, \dots, X_n)$ .

The structure function,  $\phi$ , can then be written:

$$\phi(\mathbf{X}) = egin{cases} 1 & ext{if } \sum_{i=1}^n X_i \geq k \ 0 & ext{otherwise.} \end{cases}$$

# An *n*-out-of-*n* system = A series system

An *n*-out-of-*n* system is the same as a series system:

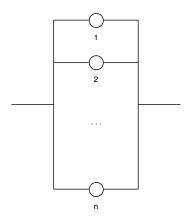

Figure: A reliability block diagram of an *n*-out-of-*n* system.

#### A 1-out-of-*n* system = A parallel system

A 1-out-of-*n* system is the same as a parallel system:

# A 2-out-of-3 system

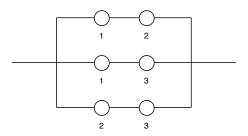

Figure: A reliability block diagram of a 2-out-of-3 system.

For a 2-out-of-3 system to function 2 out of 3 components must function. There are 3 possible subsets of components which contains 2 components:  $\{1,2\}$ ,  $\{1,3\}$ ,  $\{2,3\}$ .

# A 2-out-of-3 system

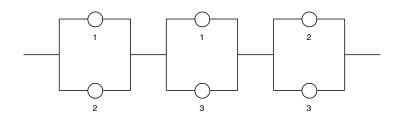

Figure: A reliability block diagram of a 2-out-of-3 system.

For a 2-out-of-3 system to fail 2 out of 3 components must fail. There are 3 possible subsets of components which contains 2 components:  $\{1,2\}, \{1,3\}, \{2,3\}.$ 

# A 3-out-of-4 system

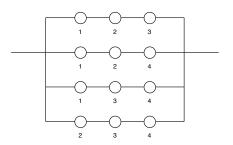

Figure: A reliability block diagram of a 3-out-of-4 system.

For a 3-out-of-4 system to function 3 out of 4 components must function. There are 4 possible subsets of components which contains 3 components:  $\{1,2,3\}$ ,  $\{1,2,4\}$ ,  $\{1,3,4\}$ ,  $\{2,3,4\}$ .

# A 2-out-of-4 system

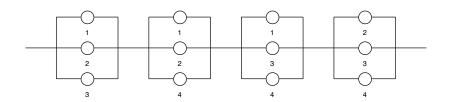

Figure: A reliability block diagram of a 2-out-of-4 system.

For a 2-out-of-4 system to fail 3 out of 4 components must fail. There are 4 possible subsets of components which contains 3 components:  $\{1,2,3\}, \{1,2,4\}, \{1,3,4\}, \{2,3,4\}.$ 

# The reliability of a *k*-out-of-*n* system

In order to evaluate the reliability of a k-out-of-n system it is convenient to introduce the following random variable:

$$S = \sum_{i=1}^{n} X_i.$$

Thus, *S* is the number of functioning components. This implies that:

$$h = P(\phi(X) = 1) = P(S \ge k).$$

# The reliability of a *k*-out-of-*n* system (cont.)

If the component states are *independent*, and the component reliabilities are all *equal*, i.e.,  $p_1 = \cdots = p_n = p$ , the random variable S is a binomially distributed random variable, and we have:

$$P(S=i) = \binom{n}{i} p^{i} (1-p)^{n-i}.$$

Hence, the reliability of the system is given by:

$$h(\mathbf{p}) = h(p) = P(S \ge k) = \sum_{i=k}^{n} {n \choose i} p^{i} (1-p)^{n-i}$$

# The reliability of a 2-out-of-3 system

EXAMPLE: Let  $(C, \phi)$  be a 2-out-of-3 system where the component states are independent, and where  $p_1 = p_2 = p_3 = p$ . We then have:

$$P(S=2) = {3 \choose 2} p^2 (1-p)^1 = 3p^2 (1-p)$$

$$P(S=3) = {3 \choose 3} p^3 (1-p)^0 = p^3.$$

Hence, the reliability of the system is:

$$h = P(S \ge 2) = 3p^2(1-p) + p^3 = 3p^2 - 2p^3.$$

# The reliability of a 3-out-of-4 system

EXAMPLE: Let  $(C, \phi)$  be a 3-out-of-4 system where the component states are independent, and where  $p_1 = p_2 = p_3 = p_4 = p$ . We then have:

$$P(S=3) = {4 \choose 3} p^3 (1-p)^1 = 4p^3 (1-p)$$

$$P(S=4) = {4 \choose 4} p^4 (1-p)^0 = p^4.$$

Hence, the reliability of the system is:

$$h = P(S \ge 3) = 4p^3(1-p) + p^4 = 4p^3 - 3p^4.$$

# The reliability of a *k*-out-of-*n* system (cont.)

When the component reliabilities are unequal, explicit analytical expressions for the distribution of S is not so easy to derive.

Let S be a stochastic variable with values in  $\{0, 1, ..., n\}$ . We then define the *generating function* of S as:

$$G_{S}(y) = E[y^{S}] = \sum_{s=0}^{n} y^{s} P(S = s).$$

When a random variable S is the sum of a set of independent random variables  $X_1, \ldots, X_n$ , the generating function of S is the product of the generating functions of  $X_1, \ldots, X_n$ . By using this property it is possible to construct a very efficient algorithm for calculating the distribution of S.

We will return to this issue in an exercise.

# The reliability of a 2-out-of-3 system

EXAMPLE: Let  $(C, \phi)$  be a 2-out-of-3 system where the component states are independent with reliabilities  $p_1, p_2, p_3$ , We then have:

$$P(S = 2) = p_1p_2(1 - p_3) + p_1(1 - p_2)p_3 + (1 - p_1)p_2p_3$$
  
 $P(S = 3) = p_1p_2p_3$ 

Hence, the reliability of the system is:

$$h = p_1 p_2 (1 - p_3) + p_1 (1 - p_2) p_3 + (1 - p_1) p_2 p_3 + p_1 p_2 p_3$$
  
=  $p_1 p_2 + p_1 p_3 + p_2 p_3 - 2 p_1 p_2 p_3$ .

# The reliability of a 3-out-of-4 system

EXAMPLE: Let  $(C, \phi)$  be a 3-out-of-4 system where the component states are independent with reliabilities  $p_1, p_2, p_3, p_4$ , We then have:

$$P(S=3) = p_1 p_2 p_3 (1 - p_4) + p_1 p_2 (1 - p_3) p_4$$

$$+ p_1 (1 - p_2) p_3 p_4 + (1 - p_1) p_2 p_3 p_4$$

$$P(S=4) = p_1 p_2 p_3 p_4$$

Hence, the reliability of the system is:

$$h = p_1 p_2 p_3 (1 - p_4) + p_1 p_2 (1 - p_3) p_4$$

$$+ p_1 (1 - p_2) p_3 p_4 + (1 - p_1) p_2 p_3 p_4$$

$$+ p_1 p_2 p_3 p_4$$

$$= p_1 p_2 p_3 + p_1 p_2 p_4 + p_1 p_3 p_4 + p_2 p_3 p_4 - 3 p_1 p_2 p_3 p_4$$

# Chapter 3

Basic reliability calculation methods

#### Section 3.1

# Pivotal decompositions

# Pivotal decompositions

#### **Theorem**

Let  $(C, \phi)$  be a binary monotone system. We then have:

$$\phi(\mathbf{x}) = x_i \phi(\mathbf{1}_i, \mathbf{x}) + (\mathbf{1} - x_i) \phi(\mathbf{0}_i, \mathbf{x}), \quad i \in C.$$
 (1)

Similarly, for the reliability function of a binary monotone system where the component state variables are independent, we have

$$h(\boldsymbol{p}) = p_i h(1_i, \boldsymbol{p}) + (1 - p_i) h(0_i, \boldsymbol{p}), \quad i \in C.$$
 (2)

# Pivotal decompositions (cont.)

PROOF: Let  $i \in C$ , and consider two cases:

CASE 1.  $x_i = 1$ . Then the right-hand side of (1) becomes:

$$\phi(\mathbf{1}_i, \mathbf{x}).$$

Hence,  $\phi(\mathbf{x}) = \phi(\mathbf{1}_i, \mathbf{x})$ , so (1) holds in this case.

CASE 2.  $x_i = 0$ . Then the right-hand side of (1) becomes:

$$\phi(\mathbf{0}_i, \mathbf{x}),$$

Hence,  $\phi(\mathbf{x}) = \phi(0_i, \mathbf{x})$ , so (1) holds in this case as well.

Equation (2) is proved by replacing the vector  $\mathbf{x}$  by  $\mathbf{X}$  in (1), and taking the expectation.

# Pivotal decompositions (cont.)

#### Corollary

Let  $(C, \phi)$  be a binary monotone system. We then have:

$$\phi(\mathbf{x}) = x_i x_j \phi(1_i, 1_j, \mathbf{x}) + x_i (1 - x_j) \phi(1_i, 0_j, \mathbf{x}) + (1 - x_i) x_j \phi(0_i, 1_j, \mathbf{x}) + (1 - x_i) (1 - x_j) \phi(0_i, 0_j, \mathbf{x}), \quad i, j \in C.$$

Similarly, for the reliability function of a binary monotone system where the component state variables are independent, we have:

$$h(\mathbf{p}) = p_i p_j h(1_i, 1_j, \mathbf{p}) + p_i (1 - p_j) h(1_i, 0_j, \mathbf{p}) + (1 - p_i) p_j h(0_i, 1_j, \mathbf{p}) + (1 - p_i) (1 - p_j) h(0_i, 0_j, \mathbf{p}), \quad i, j \in C.$$

PROOF: Use the pivotal decomposition theorem. Then apply the same theorem to  $\phi(\mathbf{1}_i, \mathbf{x})$  and  $\phi(\mathbf{0}_i, \mathbf{x})$ .

# Series and parallel components

#### Definition

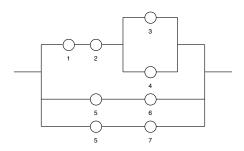

Let  $(C, \phi)$  be a binary monotone system, and let  $i, j \in C$ .

We say that *i* and *j* are *in series* if  $\phi$  depends on the component state variables,  $x_i$  and  $x_j$ , only through the product  $x_i \cdot x_j$ .

We say that i and j are in parallel if  $\phi$  depends on the component state variables,  $x_i$  and  $x_j$ , only through the coproduct  $x_i \coprod x_j$ .

In this system components 1 and 2 are in series, while components 3 and 4 are in parallel. Note, however, that components 5 and 6 are *not* in series since component 5 is also connected via component 7. Moreover, components 6 and 7 are in parallel.

#### **Theorem**

Let  $(C, \phi)$  be a binary monotone system, and let  $i, j \in C$ . Moreover, assume that the component state variables are independent.

If i and j are in series, then the reliability function, h, depends on  $p_i$  and  $p_i$  only through  $p_i \cdot p_i$ .

If i and j are in parallel, then the reliability function, h, depends on  $p_i$  and  $p_j$  only through  $p_i \coprod p_j$ .

PROOF: If *i* and *j* are in series, we have:

$$\phi(\mathbf{1}_{i}, \mathbf{0}_{j}, \mathbf{x}) = \phi(\mathbf{0}_{i}, \mathbf{1}_{j}, \mathbf{x}) = \phi(\mathbf{0}_{i}, \mathbf{0}_{j}, \mathbf{x}).$$

Thus, by pivotal decomposition we have:

$$\phi(\mathbf{x}) = x_i x_j \phi(1_i, 1_j, \mathbf{x}) + x_i (1 - x_j) \phi(1_i, 0_j, \mathbf{x}) + (1 - x_i) x_j \phi(0_i, 1_j, \mathbf{x}) + (1 - x_i) (1 - x_j) \phi(0_i, 0_j, \mathbf{x}) = (x_i x_j) \cdot \phi(1_i, 1_j, \mathbf{x}) + (1 - (x_i x_j)) \cdot \phi(0_i, 0_j, \mathbf{x}).$$

Hence, by replacing the vector  $\mathbf{x}$  by  $\mathbf{X}$  and taking expectations we get:

$$h(\mathbf{p}) = (p_i p_j) \cdot h(1_i, 1_j, \mathbf{p}) + (1 - (p_i p_j)) \cdot h(0_i, 0_j, \mathbf{p}).$$

That is, h, depends on  $p_i$  and  $p_i$  only through  $p_i \cdot p_i$ .

If *i* and *j* are in parallel, we have:

$$\phi(\mathbf{1}_i, \mathbf{1}_j, \mathbf{x}) = \phi(\mathbf{1}_i, \mathbf{0}_j, \mathbf{x}) = \phi(\mathbf{0}_i, \mathbf{1}_j, \mathbf{x}).$$

Thus, by pivotal decomposition we have:

$$\phi(\mathbf{x}) = x_i x_j \phi(1_i, 1_j, \mathbf{x}) + x_i (1 - x_j) \phi(1_i, 0_j, \mathbf{x}) + (1 - x_i) x_j \phi(0_i, 1_j, \mathbf{x}) + (1 - x_i) (1 - x_j) \phi(0_i, 0_j, \mathbf{x}) = (x_i \coprod x_j) \cdot \phi(1_i, 1_j, \mathbf{x}) + (1 - (x_i \coprod x_j)) \cdot \phi(0_i, 0_j, \mathbf{x}).$$

Hence, by replacing the vector  $\mathbf{x}$  by  $\mathbf{X}$  and taking expectations we get:

$$h(\boldsymbol{p}) = (p_i \coprod p_j) \cdot h(1_i, 1_j, \boldsymbol{p}) + (1 - (p_i \coprod p_j)) \cdot h(0_i, 0_j, \boldsymbol{p}).$$

That is, h, depends on  $p_i$  and  $p_j$  only through  $p_i \coprod p_j$ .

#### s-p-reductions

Consider a binary monotone system,  $(C, \phi)$  where the component state variables are independent, and let  $i, j \in C$ .

SERIES REDUCTION: If the components i and j are in series, then we may replace i and j by a single component i' with reliability  $p_{i'} = p_i p_j$  without altering the system reliability.

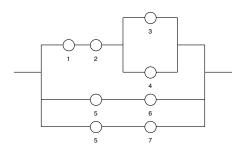

PARALLEL REDUCTION: If the components i and j are in parallel, then we may replace i and j by a single component i' with reliability  $p_{i'} = p_i \coprod p_i$  without altering the system reliability.

Series and parallel reductions are referred to as *s-p-reductions*. Each s-p-reduction reduces the number of components in the system by one.

A system that can be reduced to a single component by applying a sequence of s-p-reductions is called an *s-p-system*.

# s-p-reductions (cont.)

This 7-component system is an s-p-system. Its reliability function can be derived using s-p-reductions *only* and is given by:

$$h(\boldsymbol{p}) = [p_1 p_2 (p_3 \coprod p_4)] \coprod [p_5 (p_6 \coprod p_7)]$$
